Abstract

Antibiotic resistance is a major world-wide problem in the intensive care unit (ICU) and General ward (GW), including in India. This study thus aims to provide the evidence of the various resistivity patterns of RTI and UTI isolates. Totally 240 isolates isolated from ICU and GW units. Most common etiological organisms of RTI and UTI isolated were *Escherichia coli* (20%), and *Klebsiella spp* (19%). Most of the bacteria recovered from RTI and UTI showed the highest degree of susceptibility from Amikacin, Imipenem, Chloramphenicol, Piperacillin+tazobactam, Astreonam, Augmentin(amox+clav), Cefotaxime, Gentamycin, Netilmycin, Tobramycin, Meropenem and Ofloxacin.

Keywords: Antibiotic resistance, ICU and GW units, RTI and UTI.

Introduction

Antimicrobial resistance has become a serious public health problem worldwide. Infections caused by resistant bacteria are associated with increased morbidity and mortality than those caused by susceptible pathogens (Asati, 2013; Travers and Barza, 2002). Infections caused by resistant bacteria led to prolonged hospital stays, increased health care costs and in many cases to untreatable infections (Byarugaba, 2004).

Antimicrobial-resistant pathogens, including methicillin resistant *Staphylococcus aureus* (MRSA) (community associated (CA-MRSA) and healthcare-associated (HA-MRSA), vancomycin-resistant *Enterococcus* species (VRE), penicillin-resistant *Streptococcus pneumoniae*, extended-spectrum b-lactamase (ESBL)-producing *Escherichia coli* and *Klebsiella* species,(2-3) and fluoroquinolone - resistant and carbapenem

resistant members of the family *Enterobacteriaceae* and *Pseudomonas aeruginosa* are increasing in prevalence globally (Lockhart *et al.*, 2007; Pitout *et al.*, 2005).

Prevention of the emergence and dissemination of resistant microorganisms will reduce adverse events and their attendant costs. Appropriate antimicrobial stewardship that includes optimal selection, dose, and duration of treatment, as well as control of antimicrobial use, will prevent or slow the emergence of resistance among microorganisms (Shlaes *et al.*, 1997). Development of AM resistance pattern is directly proportional to the volume of antimicrobial consumed. Therefore, to reduce the development of antimicrobial resistance usage regulation is essential (Sharma and Barman, 2010). Monitoring the use of antimicrobials and review of sensitivity patterns are imperative. Audit of antimicrobial

sensitivity patterns in ICUs and critical care units (CCUs) are crucial and far more important for giving effective treatment and decreasing the spread of resistance.

The present study was, therefore, designed to audit the antimicrobial sensitivity pattern of microbial isolates from patients in intensive care units (ICUs) and GW of a tertiary care hospital in Tamil Nadu, India.

Materials and Methods

Clinical samples of RTI and UTI received in microbiology laboratory were considered from ICU and GW units of the hospital. A total of 951 samples from ICU unit and GW unit suspected to be having respiratory tract infection and urinary tract infection were cultured and further analyzed. Exclusion criteria were patients already on antibiotic therapy. At 37°C for 24 hours of incubation, predominant growth (on Nutrient agar, blood agar, MacConkey s agar) of single bacteria was seen in 240 isolates. The bacterial isolates were identified and confirmed using standard microbiological method which included Gram staining, colonial morphology on media, and growth on selective media, lactose fermentation, catalase, oxidase, coagulase, indole, citrate utilization, urease tests and hanging drop preparation for motility (Collee *et al.*, 1996).

Antibiotic susceptibility testing was performed by the disc diffusion assay on Muller Hinton Agar by

Kirby-Bauer method (Collee *et al.*, 1996) using the following antibiotics disc: Amikacin, ampicillin, astreonam, augmentin(amox+clav), Cefaclor, cefazolin, cefotaxime, ceftazidime, ceftriaxone, cefuroxime, cephalixin, chloramphenicol, ciprofloxacin, clindamycin, cloxacillin, co-trimoxazole, doripenem, ertrapenem, erythromycin, furozolidine, gentamycin, Imipenem, linizolid, magnex(cefaperazone+sulbactum), meropenem, nalidixic acid, netilmycin, Nitrofurantoin, norfloxacin, ofloxacin, oxacillin, penicillin, piperacillin+tazobactum, teicoplanin, Tetracycline, tobramycin and vancomycin. Interpretation of diameter of growth inhibition zone was done by using the standard interpretative chart provided by disc manufacturer. At 37°C, after 24 hours of incubation, organisms were scored as sensitive or resistant to corresponding antibiotic on the basis of zone of inhibition following the criteria of Clinical and Laboratory Standards Institute (Sumera Sabir *et al.*, 2014).

Results and Discussion

The isolation pattern of organisms as well as infection pattern is given in Table 1. The most frequently isolated organisms were *E.coli* (20.8 %) and *K. pneumoniae* (19.5 %) in both sputum and urine samples of RTI and UTI patients. The *Proteus* sp, *Salmonella* sp and *Serratia* sp were obtained very minimum level of 0.5%.

K. pneumonia, the predominant etiologic organism of RTI in this study showed moderate to high susceptibility to the Imipenem and varying degree of susceptibility to other commonly used antibiotics. *E. coli*, the predominant etiologic organism of UTI in this study showed moderate to high susceptibility to the fluoroquinolones (ciprofloxacin) and varying degree of susceptibility to other commonly used antibiotics (Table 1 and 3). Earlier studies conducted in Nigeria by Ehinmidu (2003), in Kuwait by Al Sweih *et al.* (2005), in India by Tambekar *et al.* (2006) have reported good susceptibility of the bacteria to fluoroquinolones. However, resistance to fluoroquinolones is on the increase in the locality of our study.

The isolated bacteria showed wide differences in their susceptibility to the tested antimicrobial antibiotics (Table 2 and 3). Most of the bacteria recovered from RTI showed the highest degree of susceptibility from Amikacin, Imipenem, Chloramphenicol, Piperacillin+tazobactam, Astreonam, Augmentin(amox+clav), Cefotaxime, Gentamycin, Netilmycin, Tobramycin, Meropenem and Ofloxacin. The same manner was also observed in UTI bacteria (Table 3)

The high prevalence of resistance to the community used antibiotics such as ampicillin, ciprofloxacin and tetracycline has caused considerable alarm (Janet, 2006; Nurullaev, 2004; Orrett *et al.*, 2006). The most effective antimicrobial agents in our study were Amikacin, Imipenem, Chloramphenicol, Piperacillin+tazobactam, Astreonam, Augmentin (amox+clav), Cefotaxime, Gentamycin, Netilmycin, Tobramycin, Meropenem and Ofloxacin for Gram negative bacilli and Gram positive cocci. Based on the results of this study, the efficacy of amikacin was comparable to other reports (Kothari *et al.*, 2008). In a recent study done by Devanand Prakash and Ramchandra Sahai Saxena in adjoining Meerut city, their bacterial isolates were comparable to our study, nalidixic acid was found to be the most resistant drug followed by ceftazidime. In their study most sensitive drug against all uropathogens was meropenem followed by imipenem (Devanand Prakash and Ramchandra Sahai Saxena, 2013).

In conclusion, the data obtained from this study suggest that while RTI and UTI causing pathogens are still susceptible to the imipenem and ciprofloxacin, resistance to these antibiotics is on the increase. Other commonly prescribed antibiotics in RTI and UTI such as nalidixic acid, tetracycline, Erythromycin, ampicillin, Linezolid, Penicillin are rather ineffective and may have lost their value in the chemotherapy of RTI and UTI. It is concluded that Gram negative bacilli (enterobacteraceae) were responsible for majority of RTIs and UTIs and most of the strains were multidrug resistant. The most common isolated bacteria from respiratory tract infection was *K. pneumonia* and urinary tract infection was *E. coli*, most effective antimicrobial agents against Gram negative bacilli were Amikacin, Imipenem, Chloramphenicol, Piperacillin+tazobactam, Astreonam, Augmentin(amox+clav), Cefotaxime, Gentamycin, Netilmycin, Tobramycin, Meropenem and Ofloxacin. Sensitivity of a RT pathogen and UT pathogen to a particular antibiotic vary from time to time and across different areas. To reduce the incidence of resistance, empirical antibiotic selection in treatment of RTI and UTI must be based on the knowledge of local prevalence of causative RT and UT pathogens and their respective antimicrobial sensitivities rather than on universal guidelines. Indiscriminate prescription and use of antibiotics must be discouraged in both community and hospital settings by continuous public awareness and education on rational antibiotic use as well as adoption of strict national antibiotic policy to regulate the prescription, sale and use of antibiotics.
